Discussion of  
Behavioural  
Patterns

## Chain of Responsibility pattern

Avoid coupling the request sender with the receiver(s).

- Request sender does not know about the receivers
- Receivers can be chained, with the first compatible one handling the request

# Chain of Responsibility

## Lecture 04

Lect. PhD.  
Arthur Molnar

### Behavioural Patterns

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

**Motivating example:** context-sensitive help within a GUI application

- GUI's are defined hierarchically, with each component having a parent
- Each component might handle a help request by providing a help handler
- In case a component does not provide context-based help, its parent should do it

# Chain of Responsibility

**Command**

Iterator

Mediator

Memento

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## Command pattern

Encapsulate a request as an object.

- Allows issuing request without knowing the operation **or** the receiver(s)
- The request can be passed around between application systems, as it is encoded within an object
- The key is an abstract *Command* class that declares an interface for executing operations
- Great for implementing undo/redo 😊

# Command

## Lecture 04

**Command**

Iterator

Mediator

Memento

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

Figure: General case, from [1]

## When and how to ... command

- The pattern allows changing request dynamically, as well as reusing them (**e.g.** a *menu item* and *button* might share a command)
- Specify and queue operations for later execution
- In many cases implemented using **callbacks**
- **Commands** are first-class objects (?)
- Decoupling concrete commands from issuers and receivers makes it easy to create new ones

# Command

## Lecture 04

Lect. PhD.

**Iterator**

Mediator

Memento

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## Iterator pattern

Provide a way to access the elements of an aggregate sequentially without exposing its representation.

- You need a way to traverse an aggregate (**e.g.** list, tree, GUI widget structure)
- Separate the interface for accessing elements from the aggregate itself (avoid *interface pollution*)
- Might want to traverse the elements in different ways (**e.g.** preorder, start-end, end-start)

# Iterator

## Lecture 04

Lect. PhD.  
Arthur Molnar

### Behavioural Patterns

Intro

Chain of  
Responsibility

Command

**Iterator**

Mediator

Memento

Observer

State

Strategy

Template

Method

Visitor

Discussion of  
Behavioural  
Patterns

Figure: List iterator, from [1]

- Iterator must be supplied with the aggregate to traverse
- Some of these operations can be unified (**e.g.** have only *next()*, *hasNext()*)
- Separation between aggregate and iterator allows using several iterators over the same structure at once
- The *aggregate* and its *iterator* are coupled

# Iterator

## Lecture 04

Intro

Chain of  
Responsibility

Command

**Iterator**

Mediator

Memento

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## Implementation details:

- **Iterator robustness** - what happens if you modify the aggregate during iteration? (creating a copy of the aggregate must be avoided)
- Aggregate might have to share state with its iterators, breaking *encapsulation* (**e.g.** C++ **friend** classes)
- **NullIterator** - one that has always finished the iteration

# Iterator

Discussion of  
Behavioural  
Patterns

## Mediator pattern

Define an object that encapsulates how a set of objects interact.

- Promotes low coupling, as objects do not refer each other directly
- You can vary their interaction using the mediator (or by implementing another mediator type)
- Partitioning a system into interacting objects improves software characteristics (**e.g.** reusability, understandability, maintainability)
- Having many interconnections reduces these desirable characteristics

Observer

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## When to use Mediator

- A set of objects communicate in well-defined but complex ways
- A behaviour distributed between classes should be customized without subclassing

## Consequences

- It limits subclassing, by grouping behaviour into a class
- Simplifies communication protocols between objects
- Abstracts and centralizes control
- **Mediator** and **Observer** are related

## Memento pattern

Without violating encapsulation, capture and externalize an object's internal state, so that the object can be restored to it later.

- Useful for implementing checkpoints, rollback, undo/redo 😊
- Solves the issue of externalizing state without breaking object encapsulation

# Memento

## Lecture 04

State

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## Motivating example - a system for unlimited undo/redo

- We want to undo/redo moving shapes in a graphical editor
- Each operation is modelled as an instance of the *Command* pattern
- Each operation must keep the state that needs to be restored, a *Memento*
- The memento object stores the internal state of an *originator*
- The state of *requested from* / *restored to* the originator when needed

# Memento

Discussion of  
Behavioural  
Patterns

## Observer pattern

Define a one-to-many dependency between objects so that when one object changes state, all dependents are notified.

- Solves the problem of maintaining consistency between objects (problem is similar to *Mediator*)
- Key roles are the subject (*Observable*) and the *observer*
- One subject can have many observers, and one object can observe several subjects
- Implements the *publish-subscribe* interaction

# Observer

## Lecture 04

Template  
Method  
Visitor

Discussion of  
Behavioural  
Patterns

## Implementation details

- Observers can track more than one subject, raising the issue that notifications must provide information about the originator (**e.g.** Java's *ActionEvent.getSource()*)
- Dangling references to subjects in non-GC languages!
- **Push** (subjects sends a lot of info to subscribers) versus **pull** (subscribers further query the subject) implementations
- Subjects can provide finer-grained control regarding the actions subscribers are interested in (**e.g.** our code example)

Discussion of  
Behavioural  
Patterns

## State pattern

Allow an object to alter its behavior when its internal state changes. The object appears to change its class.

### Motivating example

- A *TCPConnection* class that manages a TCP network connection
- Connection can be in one of several **states**: established, listening, closed
- When the connection object receives requests, it responds differently depending on current **state**.
- Behaviour depends on the current state, represented using an *abstract base class* (ABC).

**State**

Strategy

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

## When to use the state pattern...

- An object's behaviour depends on its state, which changes at run-time
- Can be used to replace large conditional statements modeling behaviour

## General structure...

Figure: from [1]

## Consequences

- + Localizes state-specific behaviour and partitions it for different states
- + Makes state transitions **explicit** (changes object type), instead of **implicit** (change in object internal state)
- + State objects can be shared (using the Flyweight pattern)
  - Increases the number of classes, solution is less compact

## Implementation

- Who is responsible for defining state transitions?
  - **Context** leads to centralization
  - **State** means that state classes know about each other, but new states could be easily added

Observer  
State  
**Strategy**  
Template  
Method  
Visitor  
Discussion of  
Behavioural  
Patterns

## Consequences

- Used to define a family of related algorithms
- You can implement strategies via subclassing too, but that hardwires the implementation into the class (remember *class vs. object patterns*); you also cannot vary the implementation dynamically
- Clients have to be aware of differences between strategies (context must be aware of another class's implementation)

Patterns

## Template method

Define the skeleton of an algorithm in an operation, deferring some steps to subclasses.

### Motivating example:<sup>2</sup>

- Create an application that analyzes all kinds of documents
- At first, you only support *.doc* files
- Later, you also add support for other file types (e.g. *.pdf*, *.csv*, *.whatever*)

Template  
Method

Visitor

Discussion of  
Behavioural  
Patterns

- Most algorithm steps are common across file types
- The *extract...* and *parse...* methods are particular to the document format
- We **template them** - provide an abstract implementation that subclasses override

## When to use

- Implement invariant parts of an algorithm
- Separate differences between algorithms into new classes, and avoid code duplication
- Allow extensions to your code

## Consequences

- Templates methods are fundamental for code reuse
- Lead to the Hollywood principle<sup>3</sup>

## Similarities

- With *Factory method* pattern
- With *Strategy* pattern

## Visitor pattern

Represent an operation to be performed on the elements of a structure. Define a new operation without changing the elements it operates on.

## Motivating example<sup>4</sup>

- Develop an app that works with geographical data
- You create a large graph of available objectives
- At some point, you need the graph saved to XML

**Figure:** General case (from  
<https://refactoring.guru/design-patterns/visitor>)

Discussion of  
Behavioural  
Patterns

**Motivating example** - add a *saveToXML()* method to all node types

- Nodes model business entities, and have nothing to do with XML
- Limited access to node classes
- What is you also need *saveToJSON()*?

**Figure:** General case (from <https://refactoring.guru/design-patterns/visitor>)

## Proposed solution

- Group the functionality into a new, *visitor* class
- Separate the data structure from the algorithm processing it
- Results in two hierarchies - one for the elements being operated on, and one for the visitors
- Elements only need a new operation to *accept(Visitor v)* a visitor, regardless of its type

## When to use

- Perform the same operation on many different types
- Operations to carry out change more frequently than the structure elements

Strategy

Template  
Method

**Visitor**

Discussion of  
Behavioural  
Patterns

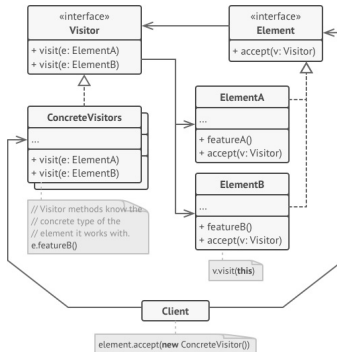

Figure: General case (from  
<https://refactoring.guru/design-patterns/visitor>)

## Consequences

- Related behaviour is grouped in the visitor class (single responsibility principle)
- Implementing new behaviour is easy (open for extension)
- Element classes are not polluted with operations
- Adding new elements is difficult, as we have to update the visitors
- Elements must expose enough info to allow visitors to do their job without breaking encapsulation

## Related patterns

- In many cases visitors are used to apply an operation over a *composite* structure
- An iterator (*internal* or *external*) can be used to visit each element in the structure

Discussion of  
Behavioural  
Patterns

**Encapsulate Variation** - describe aspects that are likely to change

- *Strategy* encapsulates an algorithm
- *State* encapsulates a behaviour that depends on a small number of states
- *Mediator* encapsulates the communication between other objects
- *Iterator* encapsulates the traversal of a data structure

# Discussion of Behavioural Patterns

Method  
Visitor  
Discussion of  
Behavioural  
Patterns

## Objects as arguments

- **Visitor** receives as argument the currently visited object
- **Command** encapsulates an operation to carry out in the future as an object
- **Memento** uses an object to "remember" an object state

# Discussion of Behavioural Patterns

## Decoupling Senders and Receivers

- *Observer* distributes communication between a *Subject* and its *Observers*
- *Mediator* encapsulates the communication - less flexible, tightly encapsulated, easier to comprehend
